Executive summary

Many protected coral species occur as bycatch in commercial fisheries around New Zealand. The Conservation Services Programme (CSP) of the Department of Conservation (DOC) recognise that Government Fisheries Observers on commercial fishing vessels are not always able to identify this bycatch at sea with high precision (especially to species level), with the confirmation of species requiring identification from a coral taxonomist in many cases. For this reason, an ongoing research project was initiated in 2016, to determine, through the examination of returned coral specimens and specimen images, the taxon and the provenance of corals bycaught in New Zealand fisheries.

This report summarises the sample and image identifications of all observed coral bycatch collected under the project during the period 1 July 2020 to 30 June 2021. A total of 43 physical specimens in 32 samples were collected by Observers and returned for identification during the reporting period. Sub-samples from each live specimen were taken for future genetic studies (n=29). Additionally, there were three historical physical samples collected by Observers with revised higher-level identifications made during the reporting period. A total of 19 research trawl-collected specimens in 15 samples are also reported here.

There were 251 specimens identified from digital images of catch reported as coral during the reporting period; 213 were protected coral taxa, and while Observers provided a label showing trip and tow number information for only 18 of the 257 processed images, all were able to be georeferenced. The remaining images were of non-protected corals. Corrected identification (where the Observer identification is revised by a coral expert), for all coral specimens and images have been amended in the COD database. Original and amended identification fields are held in COD, and all raw data extracts are provided in the Appendices and as separate excel files.

The data summaries of protected coral by-catch occurring in New Zealand region fisheries are presented by Fisheries Management Areas (FMA), fishing method, and target fishery. The greatest number of protected coral specimen counts by images came from the SOU Southland (FMA5) and SOE South East (FMA4) regions. Most were taken by bottom trawl operations targeting the deep-sea species orange roughy, and set net operations targeting school shark. Similarly, most protected corals identified from physical specimens came from SOE South-East (FMA4) bottom trawl operations targeting orange roughy.

While no formal analyses of accuracy have been carried out during this reporting period, between Observer and NIWA expert identifications, brief summaries of accuracy are provided. Agreement for some verified species identification codes are good, often down to family level, and for some groups such as stony cup corals and bubblegum corals, accurate to genus or species level. Other taxa remain problematic.

We continue to provide information to brief Observers and give input into coral guide resources including the updated and revised Deepsea Coral Guide, to help improve overall accuracy of protected coral species identification at-sea. Through this programme, we have facilitated the creation of 29 new protected coral species codes, and one non-coral code. As in previous reports, we stress in our recommendations to Observers the use of labels when images are taken, and consistency in specimen label and benthic form recording processes.

1 Background

Deep-sea protected coral samples taken as bycatch in commercial fishery operations are collected by government Observers on commercial fishing vessels. Over time, NIWA has received these coral bycatch samples and has been contracted to provide identifications. All such corals are identified by experts to the lowest feasible taxonomic level, counted, and the information reported in the relevant databases. Since 2016, this information, along with associated fishing data including fishing method, fishery area, and target fish species, have been presented in reports. All raw data have also been provided to CSP in spreadsheet form.

Data from this research helps to better characterise interactions between protected corals and commercial fishing activities (Tracey et al. 2011; Clark et al. 2019). It provides vital baseline information that can help to better inform research underpinning marine protection planning from habitat suitability modelling (e.g., Anderson et al. 2014; Rowden et al. 2017; Georgian et al. 2019), benthic risk assessments (Clark et al. 2014), and management of benthic marine protected species. It also helps to pave the way forward towards a more comprehensive mitigation framework to be implemented to protect cold-water corals in New Zealand waters.

For this project NIWA has, along with carrying out the identification of specimens, also provided:

- the identification and georeferenced labelling of images and the digital storage thereof, and
- the sub-sampling of protected coral tissue material for genetic studies (see Bilewitch & Tracey 2020a and 2020b; current DOC project *Octocoral bycatch diversity on the Chatham Rise*; and CSP 2022/23 research proposal *Documenting cryptic coral diversity in fisheries bycatch* submitted by NIWA).

The contract provides for up to 200 protected coral samples (physical specimens) and 200 specimen images to be identified per annum. Often the number of physical coral specimens identified has been exceeded because of historic samples and/or research trawl survey samples being identified in addition to recently collected Observer samples. This can also occur when international coral taxonomists have visited the NIWA Invertebrate Collection (NIC) – as part of, or separate to, this project. For this project, if time allows, a backlog of historical coral samples collected by Observers are identified, but priority is given to recent Observer collected samples from within New Zealand's Exclusive Economic Zone (EEZ), (for the current year and historical), followed by research trawl survey samples, then high-sea samples.

This project does not report on coral specimens by images photographed from the high-seas.

2 Objectives

The overall objective is as follows: to determine which protected cold-water coral species are captured in commercial fisheries, and the mode of their capture, while also building on the New Zealand cold-water coral collection sample size for use in future research.

The specific objectives for this project are:

1. To determine, through examination of returned protected cold-water coral specimens and images, the taxon, and where possible the provenance of cold-water corals killed in New Zealand fisheries (for returned dead specimens).

2. To collect sub-samples of all protected cold-water coral specimens for genetic analysis in future.
3. To assist with Observer training and the development/improvement of Observer training resources.

Here we report on all corals identified by specimens and images bycaught during the period 1 July 2020 – 30 June 2021.

3 Methods

3.1 Objective 1

Determine, through examination of returned protected cold-water coral specimens and images, the taxon, and where possible the provenance of cold-water corals killed in New Zealand fisheries (for returned dead specimens).

There are three key activities for specific objective 1:

3.1.1 Identification of returned protected coral specimens

The deep-sea coral bycatch that could not be identified by Observers at sea were retained (whole specimens or sub-samples of the specimens) and delivered to NIWA for identification. A similar method used to process bycatch of invertebrates (excluding protected corals) collected by Observers under a Fisheries New Zealand (FNZ) project *Identification of benthic invertebrate samples from research trawls and observer trips*, (Mills et al. 2020; Schnabel et al. 2021), was followed.

High-seas samples were not differentiated from within-EEZ samples at the time of arrival at NIWA for processing. Trip data are provided on sacks of frozen material but no information on general location is given at this stage. Once the frozen sacks have thawed it is most efficient to process all of their contents rather than separating and refreezing high-seas samples. As such, high-seas samples are partially processed within this project. The high-seas samples are a very useful contribution to habitat suitability modelling exercises in the high-seas (e.g., see Georgian et al. 2019).

The corals were thawed, sorted into main groups and initially identified to coarse taxonomic level (mostly to order and family level). The tasks of fixing and preserving samples, providing containment (jar or pail storage), documenting samples (station numbering, labelling) and high level sorting (dividing samples into major or minor taxonomic groups in the laboratory), were all carried out under the FNZ project *Data Custodianship Services*. Sample data were entered into the web-interfaced NIWA Observer Samples Database (version 2.3.1; 2020), then returned to frozen storage, fixed in ethanol, or dried where appropriate.

A catalogue of all samples/specimens received by NIWA was provided to the NIWA Invertebrate Collection (NIC) Manager. Data from OSD were uploaded into the NIC Specify database *niwainvert* and the specimens were curated for formal taxonomic identification.

Experts then identified all corals to the species level wherever possible and when this was not possible, to genus or family level, and assigned the most appropriate three-letter Ministry for Primary Industries (MPI) code (noting that coral codes have not yet been allocated for all coral taxa recognised by experts). Specimen handling followed NIWA procedures for identifying specimens housed in the NIC. NIWA currently manages specimens according to the “Guidelines for the care of

natural history collections” (Committee on Common Philosophies and Objectives, 2010). NIWA also has its own collection policy document: “NIWA Marine Invertebrate Collection Policy and Procedures”, which also guided the process. Specimens retained in the NIC are held in stewardship for DOC.

Expert identification of the samples was carried out and updated species names and counts were entered into *niwainvert*. See Table 3-1 for the list of experts that carried out identifications.

Table 3-1: Experts, their affiliation and their speciality.

Expert	Affiliation	Taxon Group
Di Tracey	NIWA	Scleractinia, gorgonian octocorals
Peter Marriott	NIWA	Stylasteridae, Coralliidae
Rob Stewart	NIWA	Antipatharia
Jaret Bilewitch	NIWA	Plexauridae, Acanthogorgiidae, other gorgonian octocoral groups
Diana Macpherson	NIWA	Hydrozoa (excluding Stylasteridae)
Dennis Gordon	NIWA	Bryozoa
Scott Nodder	NIWA	Rocks
Sadie Mills	NIWA	Ophiuroidea
Dr Stephen Cairns	Smithsonian Institution, USA	Primnoidae
Dr Marcelo Kitahara	Universidade Federal de São Paulo, Brazil	Scleractinia
Dennis Opresko	Smithsonian Institution, USA	Antipatharia
Dr Phil Alderslade	Previously CSIRO, Hobart, Australia	Keratoisididae

3.1.2 Updating species identifications in the FNZ Centralised Observer Database (COD)

Sample information of expert-identified coral specimens collected by Observers for this reporting period were extracted from Specify database *niwainvert* and provided to the COD database manager for loading and table updates. NIWA manages the COD database for FNZ and it is regularly updated with revised identifications when corals are returned from sea (Tracey & Mills 2016). In this process the generic three-letter MPI codes initially used by Observers to record unidentified corals, are updated with revised codes based on the expert identification. For example, SIA (Scleractinia) to COF (Flabellum cup coral).

These updates made to COD allow for the potential interactions between individual coral taxa and fishing gear to be better quantified, and therefore help to identify factors that may have contributed to coral mortality.

3.1.3 Processing and identification of specimens from images

A document prepared for Observers collecting coral data at sea was provided to CSP and, following their approval, forwarded to the Observer Services Unit of the FNZ Observer Programme in early 2017 (*Instructions to observers when carrying out at-sea protected coral data collection* (Tracey & Mills 2016)). Specifically, it was emphasised that images were to be captured in a well-lit area using a plain grey background if possible, and a reference size scale, with a specimen label showing trip, species code, and tow numbers and the Observer’s name included in the image. The name of the

Observer taking the image was to be retained, as this is important for feedback, training, and acknowledgement.

Identifications of the specimens and their associates, such as another coral attached to the specimen, shown in the images were carried out by coral and non-coral experts (Table 3-1).

The provenance of the specimens captured in the images were determined (where possible), using the trip and tow numbers shown on the label in the image to extract tow coordinates from COD. Specimens in images that were determined to be from outside New Zealand's EEZ (i.e., collected within high-sea Fishery Management Area's: Challenger Plateau (CET), Lord Howe Rise (HOWE), Louisville Ridge (LOUR), Three Kings Rise (TKET) and Wanganella Bank (WANB)), were not identified by experts.

Efforts were made to determine tow numbers, if they were not shown on the labels in the Observer images, by using the trip number and the date and time stamp of images (extracted from the digital image properties) together with the FNZ photographic logs and 'Benthic Materials' forms. Location details were extracted for the trip and the likely tow number from the COD database. By applying these methods, we were, with a reasonable degree of confidence, able to assign a tow number to several such images and therefore produce georeferenced images. Metadata for the images, including provenance data, were then assembled manually in a spreadsheet. The following metadata were embedded into each image file where available:

- expert ID in the form of taxonomic name (species, genus or family level)
- trip and tow number
- initial Observer ID and expert ID in the form of three-letter MPI species code
- specimen count
- specimen comments
- keywords relevant to the subject of the image
- the NIWA Invertebrate Collection catalogue number (where applicable)
- image rating (where the best rating is 1 (very good quality) and the worst is 5 (very poor quality))

An image rating classification was developed specifically for this project as there is no universal standard (International Press Telecommunications Council 2019). Image ratings help indicate the quality and usefulness of an image and as part of the workflow, enable the images to be sorted and filtered at a later point in time. Table 3-2 shows the image rating classification used and outlines the factors taken into consideration when assigning a rating to an image.

Table 3-2: The classification system used to assign a rating to an image.

Image rating	Classification
1	Very good quality. The specimen is in focus and the whole specimen has been photographed. Good lighting and background. The image includes a label with complete data. There may also be a scale present. The specimen weight may also be shown in the image.

-
- 2** Good quality. All the specimen, or part of the specimen is in focus. The lighting and background is sufficient. The image includes a label with some or complete data. May include more than one coral specimen. There may also be a scale present. The specimen weight may also be shown in the image.
 - 3** Average quality. All the specimen, or part of the specimen is in focus. The image may include a label with some data, and a specimen weight may be shown. Insufficient lighting and background. May include more than one coral specimen.
 - 4** Bad quality. All the specimen, or part of the specimen may be in focus, or in focus enough to be able to determine what it is. There is no label in the image. It is not photographed against a good background with a scale and good lighting, and/or photographed at an unhelpful angle. The image is of an aggregated group of corals and other specimens, so it is not clear what the subject of the image is. The image is of a non-coral.
 - 5** Very bad quality. The specimen, or part of the specimen is out of focus and is not able to be identified to a sufficient taxonomic level as a result. There is no label in the image. It is not photographed against a good background with a scale and good lighting, and/or photographed at an unhelpful angle. The image is of an aggregated group of corals and other specimens, so it is not clear what the subject of the image is. The image is of a non-coral.
-

Using the ACDSee Photo Studio Professional 2020 (version 13.0) software to manage the metadata information, data for each image was either added manually into the relevant field or assigned from a drop down ‘picklist’. These data were then embedded in the image file.

Finally, trip, tow and fishery data sourced from COD for each specimen by image were added to the spreadsheet. Data included position (the start and end coordinates of the tow that sampled the photographed coral), depth (minimum and maximum depths), along with the collected date, fishing method, target species, and Observer-reported Fisheries Management Area in which the coral was caught (see Figure 4-1).

3.2 Objective 2

Collect sub-samples of all protected cold-water coral specimens for genetic analysis in future.

Tissue sub-samples were taken from all live-collected protected coral samples provided to NIWA by Observers. The sub-samples were stored with their corresponding NIC registration label in standard vials in 99% high grade absolute ethanol. The subsamples are currently stored in the NIC wet collection along with the parent samples.

3.3 Objective 3

Assist with Observer training resources.

To meet this objective, resources such as the Instructions to observers when carrying out at-sea protected coral data collection (Tracey & Mills 2016), and any recommendations which have been highlighted in these reports, are regularly passed on to CSP representatives when requested to assist with Observer training.

Input into the development and improvement of Observer training resources such as revised guide material and expert review of material has also been provided.

4 Results

4.1 Objective 1

4.1.1 Identification of returned protected coral specimens

During the reporting period 1 July 2020 to 30 June 2021, NIWA received and processed 32 Observer-collected protected coral samples containing 43 specimens, and 3 historical (i.e., collected prior to the current reporting year) samples (3 specimens), identified since delivery of the previous progress report (Macpherson et al. 2021b).

A summary of these 35 samples (46 specimens) identified by experts are provided in extracts from the NIWA Invertebrate Collection (NIC) Specify Database *niwainvert* (Appendix A (a–b)). One of the historical samples was a re-identification of a black coral specimen as newly described species *Bathyphantes pseudoalternata*, which was examined and illustrated in Molodtsova et al. (2022).

Additionally, 4 research trawl-collected protected coral samples (4 specimens) collected between July 2020 and June 2021, and 11 historical trawl survey samples (15 specimens) are included in this summary (see Appendix A(c)). These trawl survey samples were included for identification due to the low number of returned Observer collected specimens as stated in the contract for this project (Attachment 1 – NIWA Expanded Methodology, section 1.3: "...priority will always be given to the Observer collected protected corals, then to research trawl samples, then ET samples."). It is time-efficient for the experts to look at the specimens simultaneously.

While no formal 'analyses of accuracy' have been carried out between the Observer and NIWA expert identifications, such as those presented in Parker et al. (2009), a summary of the accuracy of Observer ID is presented and will be useful for on-going Observer training exercises. We note that the sample sizes we are commenting on are small. For the current reporting year, Observers correctly identified 20 of the 32 samples, with one correctly identified to genus or species level (Bubblegum coral *Paragorgia arborea* and *P. spp.*, PAB), three to family or family group level (stony cup corals - CUP, and Stylasteridae - COR), nine to order level (Antipatharia - COB, Scleractinia - SIA) and seven to phylum level (unidentified coral code - COU). This indicates a 60% accuracy of Observer code use overall for the physical samples, regardless of the taxonomic level of the ID (see colour coding and final column of Appendix A(a)).

Eleven of the samples were incorrectly identified by Observers, however the identifications were within the correct coral class (one sample), order (six samples) or family level (four samples). One of the codes used was UNI, i.e., the Observer could not identify the sample. Observers correctly identified specimens to at least order level approximately half of the time (15 samples with correct ID, or incorrect but at least acceptable to order level = 46%); to family level 22% of the time (7 samples with correct ID correct, or incorrect but at least acceptable to family level); and or to species level 3% of the time (1 sample with ID correct to species level) (Appendix A(a)).

4.1.2 Summary of physical specimen data loading processes into COD

The revised identifications from the *niwainvert* database were provided for uploading into COD. The COD extract summary is provided in Appendix B.

Of the 35 rows of Observer-collected physical specimen data (32 current year, 3 historical) provided for uploading into COD:

- 24 rows were able to be matched to the catch record for the specimen and were updated.
 - Note that the Observer ID code sometimes differs between the specimen label and the code entered onto the benthic form. Often an improved higher-level identification code was entered into the benthic form. As an example, the generic black coral code COB was entered on a specimen label but then changed to species code LEI (*Leiopathes secunda*) on the benthic form. These types of inconsistencies create some difficulties when matching codes during the COD database updates and highlight how important it is to have the additional MPI sample number from the benthic form and sample label to assist with the data update process.
- 10 rows were not able to be matched to the catch record for the specimen and so had to be inserted as new records. A non-match could occur when:
 - a sample lot has more than one species in it (which could include non-corals) so has been split to numerous rows, one of which is the original record,
 - a three-letter code written on the specimen label does not match the code written on the benthic form and/or the MPI sample number was incorrect or not provided, hence the sample and COD record cannot be reconciled,
 - an observer has forgotten to record the returned specimen in the catch form,
 - historical samples are more likely not to match and this was the case for all three historical samples included in this year's identifications. It is noted that sample matching is improving over time.
- 1 row was not able to be entered because no benthic form was received from FNZ for TRIP6330. A request has been made to FNZ at time of writing and the specimen record will be updated (matched and / or inserted) when this is entered to COD.

4.1.3 Data summaries and locality plots for physical sample identifications

Data summaries for the physical specimens identified from Observer collected protected coral samples in the reporting year (1 July 2020–30 June 2021), are provided below. These include a count by Fisheries Management Area (FMA) (Table 4-1) and a count of tows and specimens by fishing method and target fishery (Table 4-2). Also see Figure 4-1 that illustrates the geographic spread of physical sample coral by-catch in the region. A high-seas region (ET), sample is included in Figure 4-1.

Table 4-1: Summary of protected coral samples by Fisheries Management Area (FMA) or from high-seas regions (ET), for Observer collected protected coral samples. Collected during the current reporting year (1 July 2020–30 June 2021)

FMA	Description	Count of samples
SOE	South-East (FMA4)	18
CEE	Central East (FMA2)	6
AKE	Auckland East (FMA1)	4
CHA	Challenger/Central Plateau (FMA7)	1
SEC	South-East (Coast) (FMA3)	1

FMA	Description	Count of samples
SOU	Southland (FMA5)	1
CET	Challenger Plateau (ET)	1
Total	All areas	32

(b) Historical samples identified in this reporting period but collected prior to July 2020.

FMA	Description	Count of samples
AKE	Auckland East (FMA1)	1
SOU	Southland (FMA5)	1
SOI	Southern Offshore Islands - Auckland & Campbell Is. (FMA 6A)	1
Total	All areas	3

Table 4-2: Count of tows and specimens by fishing method and target fishery for physical specimens. BLL = Bottom Longlining; BT = Bottom Trawl; MW = Midwater Trawl; PRB = Precision Seafood Harvesting Bottom Trawl. Samples collected in the current reporting year (1 July 2020–30 June 2021).

Target Fishery (common name)	FNZ Code	Fishing method	Count of tows	Count of specimens
Orange roughy	ORH	BT	16	21
		MW	1	1
Hoki	HOK	BT	2	6
		PRB	1	2
Alfonsino & long-finned beryx	BYX	BT	4	4
Snapper	SNA	BLL	3	3
Ling	LIN	BLL	2	4
Arrow squid	SQU	BT	1	1
Smooth oreo	SSO	BT	1	1
All	—	All	32	43

(b) Historical samples identified in this reporting period but collected prior to July 2020

Target Fishery (common name)	FNZ Code	Fishing method	Count of tows	Count of specimens
Orange roughy	ORH	BT	1	1
Oreos	OEO	BT	1	1
Smooth oreo	SSO	BT	1	1
Total			3	3

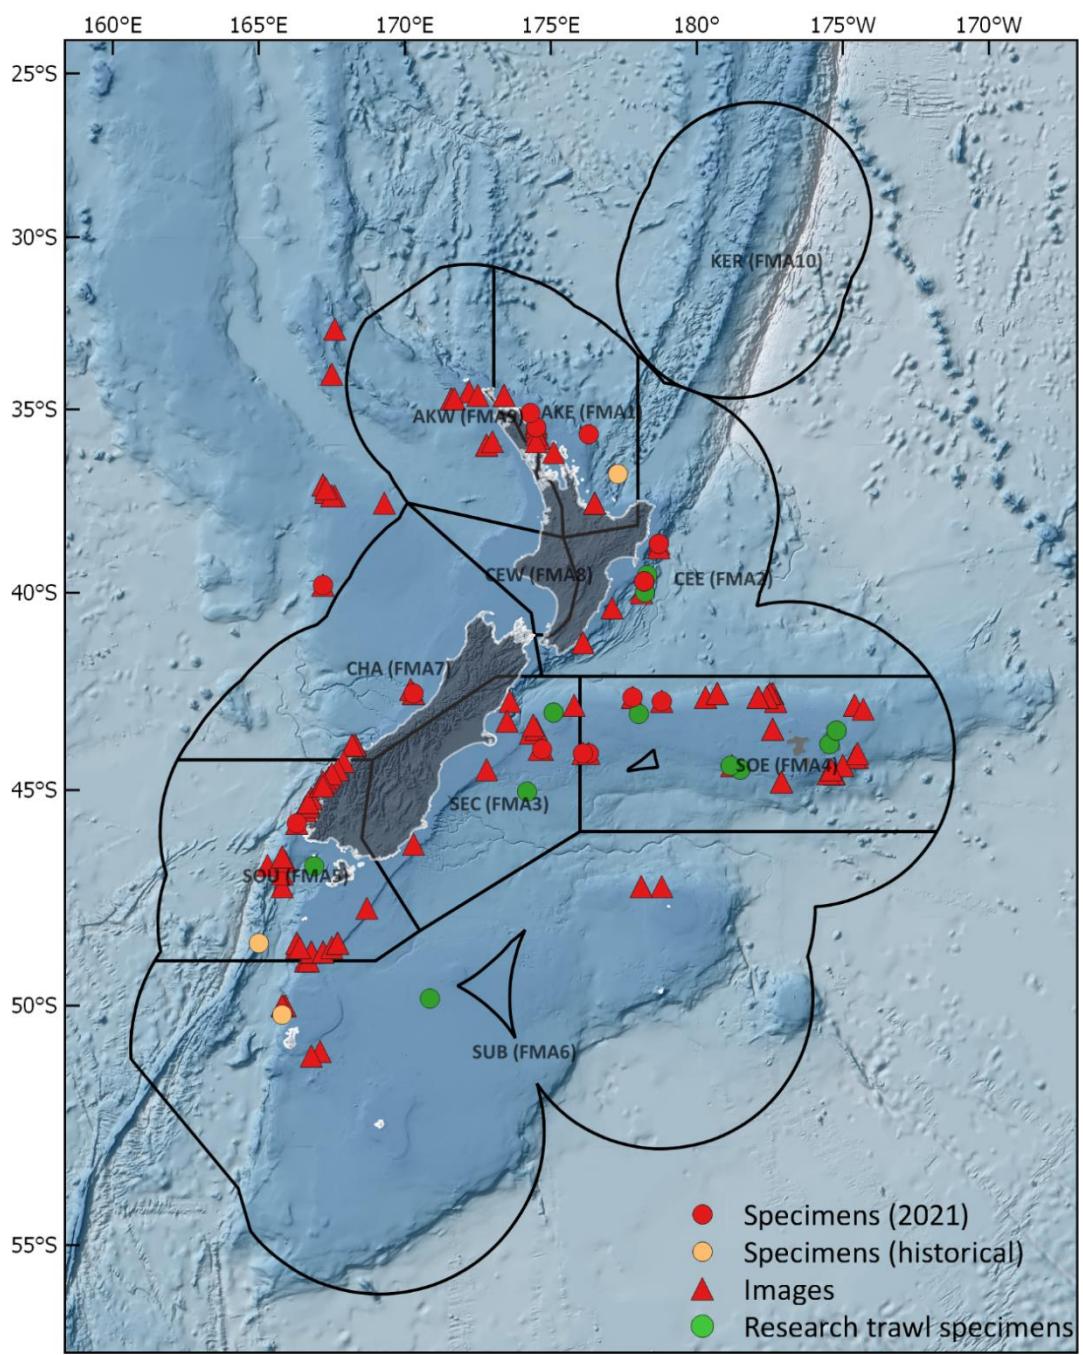

Figure 4-1: Location of identified protected coral samples (65 physical specimens; 251 digital image specimens) within Fisheries Management Areas (FMAs). Physical specimens (circles), and images data (triangles). 2021 = current reporting year 1 July 2020–30 June 2021.

4.1.4 Data processing and identification of specimens from digital images

During the reporting period 1 July 2020 to 30 June 2021, NIWA received 356 digital images and 257 of these were processed. The remaining 99 were not processed either because they were of non-protected coral taxa, or they were of coral bycatch taken outside of New Zealand's EEZ. Note, however, that some images taken outside of NZ's EEZ were mistakenly processed since the image was identified by an expert before it was georeferenced.

In total, 251 specimens were identified from the 257 images that were processed (the numbers differ as sometimes there are multiple images of the same specimen). Of the 251 specimens, 213 were protected coral taxa, and all of them were able to be georeferenced. The remaining 38 specimens were determined to be non-protected taxa: bryozoans, algae, sponges, rocks, hydroids, soft corals, stalked crinoids, zoanthids, and snake stars. Many of these taxa were associated with large protected *Antipathella* spp. black corals (Appendix C).

Observers provided a label showing trip and tow number information for only 18 of the 257 processed images. Tow numbers for the remaining images were able to be determined to a reasonable degree of accuracy by either:

- using COD database and the image timestamp to cross check the trip tow start and tow end date and time details already entered in COD, in the FNZ photographic logs, and on the 'Benthic Materials' form, or
- by cross checking the images with specimen records already entered in the *niwainvert* database as some specimens that had been photographed were also sent to NIWA by the Observer and they had a label indicating the tow number. This method applied to 33 specimens in 27 sample lots.

The highest number of digital images of protected coral species was of the hydrocoral *Errina novaezelandiae* (28 specimens), followed by octocoral species belonging to family Plexauridae (16 specimens), black coral *Antipathella fiordensis* (13 specimens), and bubblegum coral *Paragorgia* spp. (11 specimens). A range of genera and species from octocoral family Primnoidae (sea fans, sea whips) were well represented in the analysed images. A diverse range of Antipatharia (black corals) and Scleractinia (stony corals) were also present (Table 4-3; Figure 4-2).

Table 4-3: Count of imaged specimens identified by species.

Phylum	Class	Order	Family	Genus	Species	Specimen count
Annelida	Polychaeta					4
Arthropoda	Maxillopoda	Cirripedia				1
Bryozoa	Gymnolaemata	Cheilostomatida	Catenicellidae			2
	Stenolaemata	Cyclostomatida	Cerioporidae	<i>Tetrocycloecia</i>	<i>neozelanica</i>	1

Figure 4-2: A selection of representative specimen images. a) Hydrocoral *Errina novaezelandiae*; b) stony cup coral *Monomyces*; c) sea fan coral *Metafannyella*; d) sea fan coral *Acanthogorgia*; e) and f) bubblegum coral *Paragorgia*, (note the numerous small bubblegum coral colonies in image e); g) black coral *Bathypathes*; h) black coral *Antipathella fiordensis*.

During this reporting period Observers assigned identification codes for 206 specimens out of the 251 specimen images identified by experts. Observers correctly identified 157 of the specimens to at least Order level (76% accuracy). There were 49 protected coral specimens identified incorrectly by Observers as either a different protected coral species, hydroid (code HDF), soft coral (code SOC), coral unspecified (code COU) or unidentified (code UNI). Codes such as rock (code ROK) and sediment (code SED) were used presumably to indicate what the corals are attached to.

Data summaries for the specimens identified from images are provided below and include a count by Observer Fisheries Management Areas (FMA) (Table 4-4) and a count of tows and specimens by fishing method and target fishery (Table 4-5).

Table 4-4: Summary of imaged specimens by Fisheries Management Area (FMA), ranked by specimen count.

Area	Description	Total no. of specimens
SOU	Southland (FMA5)	73
SOE	South East (FMA4)	67
SEC	South-East Coast (FMA3)	21
CHA	Challenger (FMA7)	19
CET	Challenger Plateau, beyond the EEZ (FMA) (ET)	17
AKE	Auckland East (FMA1)	13
AKW	Auckland West (FMA9)	12
CEE	Central East (FMA2)	9
SOI	Southern Offshore Islands - Auckland & Campbell Is. (FMA 6A)	9
SUB	Subantarctic (FMA6)	9
WANB	Wanganella Bank (ET)	2
Total		251

Table 4-5: Count of tows by fishing method and target fishery for imaged specimens. BLL = Bottom Longlining; BT = Bottom Trawl; MW = Midwater Trawl; PRB = Precision Seafood Harvesting Bottom Trawl; POT = Potting; SN = Set netting

The FMAs with the highest number of coral bycatch were those around the SOU Southland (FMA5) and SOE South East (FMA4) regions. Most were taken by bottom trawl operations targeting orange roughy, and set net operations targeting school shark.

4.2 Objective 2: Sub-samples of protected coral specimens for genetic analysis

During this reporting period, tissue sub-samples were taken from 29 specimens from all live Observer collected protected coral samples. Accumulated protected coral tissue sub-samples retained for future genetic studies now number 103, and DOC projects using these samples for molecular studies have been carried out or are underway. Sub-samples of many black coral and octocoral specimens have now been analysed and the results are reported in Bilewitz & Tracey (2020a; 2020b). Currently, the genetic diversity of octocoral species in the family Primnoidae collected by Observers on the Chatham Rise is being investigated under a non-cost recovered CSP biodiversity project, using the sub-samples collected from this objective.

4.3 Objective 3: Assist with Observer training resources

Recommendations which have been highlighted in these reports, along with the instructions to Observers when carrying out at-sea protected coral and revised invertebrate data collection, including the methods used for sampling and image labelling (Tracey & Mills 2016; Tracey et al. 2019) were passed onto Observers via the CSP, to assist with on-going Observer training.

A key activity during this reporting period has been to assist with the development and improvement of Observer training resources. The focus has been on the production of a revised and updated Coral Identification Guide for use at-sea by Observers, see Macpherson et al. (2021b) for details of this work. Additionally, initial discussions around the production of a coral identification training video for Observers took place.

New three-letter MPI species codes were created to aid in the production of the guide, to help match COD data records, and to improve the accuracy of our expert identifications. A total of 29 codes were created for protected coral species of black corals, bamboo corals, sea fans and stony corals (Table 4-6). A non-coral code was also added for species of hydroid that is often confused with a coral (*Cryptolaria* sp; CRT). Some existing codes were revised for clarity and to reflect updated taxonomy. See Macpherson et al. (2021b) for further details of this work.

Table 4-6: A list of new 3-letter species codes.(see https://marlin.niwa.co.nz/species_codes/ with corresponding scientific and common name details that are now loaded into NIWA managed FNZ databases (updated from Macpherson et al. 2021b).

No assistance has been required by CSP for in-person Observer training during this reporting period although the intention with any future Observer training workshops is that it will include NIWA staff. The interactive training will follow that of the Convention for the Conservation of Antarctic Marine Living Resources (CCAMLR) Observer briefing methods used by NIWA staff annually. Training will include using coral samples from the NIC and revised guides to help with coral identification. The focus will be on using general accuracy information summaries to inform the identifications, explaining how to differentiate easily confused taxa, and re-stating sample and image collection methods and labelling.

5 Summary and conclusions

Protected corals continue to be taken as by-catch within the region, primarily from bottom trawl fishing methods but also from the bottom long-line and school shark set net fisheries. The identified samples were photographed and or collected opportunistically from commercial fishing activity when either Observers were uncertain of their identification of the coral specimen, the specimen was caught outside the expected depth range or distribution, or when the specimen was considered rare or unusual. Such samples are highly valuable and continue to augment the datasets used to highlight interactions between fishing and protected corals, for example in the modelling of species distributions and community classifications. Recognising the importance of these data for enhancing basic understanding of coral distribution and given recent elucidation of unexplored cryptic diversity in some coral groups, Observers are always encouraged to return a specimen or sub-sample of the specimen, whenever they are able to, regardless of how confident they are in their identification. Overall, the accuracy of the Observer identification is good and for some groups can be carried out to family and sometimes genus or species level. While the sample sizes used in the general accuracy summaries are small, it is clear certain taxa continue to be confused.

A total of 65 physical specimens, and 251 specimens from digital images were identified or verified to the finest taxon level possible by experts. Of the 251 digital images, 213 were of protected coral taxa and were able to be georeferenced. There were 38 digital images of non-protected coral taxa.

The number of Observer specimens photographed were high, however physical samples returned for identification from within the EEZ were low for this period (32 physical samples containing 43 actual specimens). An overall low return of samples by Observers was also noted in Schnabel et al. (2021) (FNZ Project BEN202103, previously DAE201804), where the numbers of invertebrates returned for expert identification have reduced.

6 Recommendations

For some returned physical specimens and images, the processing and identification ashore and database updates is made difficult if labelling protocols and photography instructions are not

followed. While we appreciate the workload that is placed on Observers at sea, recommendations here-in are made on their at-sea data collection methods.

Digital Images need to be taken with a label that includes trip and station data, and the coral specimen, or a sub-sample of the specimen, the MPI number, and a species code. This information helps experts verify the identification. Over time, standardised easy-to-use pre-printed labels for Observers to include in photographs should improve this process and hence the accuracy of accompanying metadata. Examples of different labelling methods used by Observers are shown by Macpherson et al. (2021a). We note the standardised use of pre-printed labels and photocards has recently progressed within FNZ (see section 2.1, Figures 1 and 2 of Schnabel et al. 2021).

The MPI sample number and the initial Observer three-letter identification code are crucial components in the data matching process used for updating the COD database with the expert ID of the physical specimens. For ease of database updates, we recommend that the initial MPI sample number and three-letter code written on the specimen label corresponds to the sample number and code on the benthic form. If Observers decide to change their identification code at a later date while filling out electronic or paper catch forms, we ask that they also amend the specimen labels to match the benthic forms.

7 Acknowledgements

We thank Te Papa Atawhai Department of Conservation, CSP Programme for their ongoing support of protected coral research in New Zealand waters, particularly Ian Angus, Manager, and Marine Species Team members Lyndsey Holland, Katie Clemens-Seely, and Shannon Weaver. We also thank FNZ Observers for their efforts at sea. The various coral experts who provided identifications for this reporting period are acknowledged. These include: Di Tracey, Rob Stewart, Jaret Bilewitch, Peter Marriott, and Diana Macpherson (NIWA) along with Stephen Cairns and Dennis Opresko (Smithsonian Institution, USA), Marcelo Kitahara (Universidade Federal de São Paulo, Brazil), and Phil Alderslade CSIRO, Australia). Our international experts willingly give their time to verify our identifications and contribute to guide updates and revisions, and this is hugely appreciated.

We acknowledge the NIWA NIC team for providing on-going curatorial support for the specimens. Finally, our thanks to Caroline Wood (NIWA) for updating the COD database and providing data extracts, and to Owen Anderson (NIWA) for his timely turn around in thoroughly reviewing this report, and Darren Parsons (NIWA Fisheries and Ecosystems Programme Leader) and Richard O'Driscoll (NIWA Chief Scientist, Fisheries), for their final comments and sign off on the report.

Appendix C Summary of digital images processed and identified for the period 1 July 2020 to 30 June 2021.

This publicly accessible website can be used to search the target species, initial and expert ID species codes: https://marlin.niwa.co.nz/species_codes/ and FMA codes: https://marlin.niwa.co.nz/area_codes/. The fishing method codes are as follows: TWL = Trawling, includes bottom trawl and midwater trawl; BLL = Bottom LongLine; SN = Set Net; BT = Bottom Trawl (single); PRB = Precision Seafood Harvesting Bottom Trawl (also referred to as MHS = Modular Harvest System); POT = Potting. Note that there can be a time lag from when CSP request the images to when they are received, and so some images can get backlogged and as a result some images from 2019 are included in this report.
